13

14 **Abstract**

15 The diffusion coefficients D_{12} of phenylbutazone at infinite dilution in supercritical CO₂ were
16 measured by the chromatographic impulse response (CIR) method. The measurements were carried
17 out over the temperature range from 308.2 to 343.2 K at pressures up to 40.0 MPa. In addition, the
18 D_{12} data of phenylbutazone at infinite dilution in ethanol were also measured by the Taylor
19 dispersion method at 298.2 to 333.2 K and at atmospheric pressure. The D_{12} value of
20 phenylbutazone increased from $4.45 \times 10^{-10} \text{ m}^2 \text{ s}^{-1}$ at 298.2 K and 0.1 MPa in ethanol to about 1.43
21 $\times 10^{-8} \text{ m}^2 \text{ s}^{-1}$ at 343.2 K and 14.0 MPa in supercritical CO₂. It was found that all diffusion data of
22 phenylbutazone measured in this study in supercritical CO₂ and in ethanol can be satisfactorily
23 represented by the hydrodynamic equation over a wide range of fluid viscosity from supercritical
24 state to liquid state with average absolute relative deviation of 5.4% for 112 data points.

1. Introduction

Supercritical fluid is a substance whose temperature and pressure are simultaneously above its critical point. Processing materials with supercritical fluid is a proven and industrially applicable technology. Supercritical CO₂ is the most widely used in research studies and industrial applications. It is non-toxic, non-flammable, chemically inert and inexpensive. Furthermore, it is a green and versatile solvent having near ambient critical temperature, and promising alternative to noxious organic solvents. The commercial application of combination of pharmaceutical and supercritical CO₂ is one of interesting research areas with significant potential [1,2]. To design and improve new supercritical process, it is needed to understand the fundamental information of the supercritical system. Estimation of mass transfer properties in supercritical fluid is required the diffusion data. Phenylbutazone, is an active pharmaceutical ingredient, which is used primarily in non-steroidal anti-inflammatory pharmaceutical that also possesses antipyretic and analgesic effects. Unfortunately, the diffusion data [3-7] are few for pharmaceutical in supercritical CO₂, and no data are available in literature for the system of phenylbutazone and CO₂. The objective of this work was to measure the diffusion coefficients D_{12} of phenylbutazone at infinite dilution in supercritical CO₂ by the chromatographic impulse response (CIR) method. And then, the D_{12} data of phenylbutazone in ethanol were also measured by the Taylor dispersion method. Furthermore, the validity of the hydrodynamic equation D_{12}/T as a function of fluid viscosity was examined for all diffusion data measured in this study.

2. Theory

The theories for the CIR and the Taylor dispersion methods have been described in detail previously [8-10], in here, briefly described. When a tracer species is pulse-injected into a fully developed laminar flow in a cylindrical column, the cross-sectional average concentration $C(t)$ can be described as follows:

$$\begin{cases}
C(t) = \left(\frac{m}{\pi R^2} \right) \frac{1}{(1+k)(4\pi Kt)^{1/2}} \exp \left\{ -\frac{(L - u_0 t / (1+k))^2}{4Kt} \right\} \\
K = \frac{D_{12}}{1+k} + \frac{1+6k+11k^2}{(1+k)^3} \frac{R^2 u_0^2}{48D_{12}} \\
k = \frac{u_0}{u} - 1
\end{cases} \quad (1)$$

where t is the time, m the amount of solute injected ($= \pi R^2 u_0 \int_0^\infty C(t) dt \equiv \pi R^2 u_0 \times (\text{peak area})$), R the radius of diffusion column, L the distance, u_0 the average velocity of fluid, and D_{12} the infinite dilution binary diffusion coefficient of the solute. The D_{12} value can be determined by minimizing the root-mean-square (rms) fitting error ε , defined by Eq. (2).

$$\varepsilon = \left(\frac{\int_{t_1}^{t_2} (C_{\text{meas}}(t) - C(t))^2 dt}{\int_{t_1}^{t_2} (C_{\text{meas}}(t))^2 dt} \right)^{1/2} \quad (2)$$

where t_1 and t_2 correspond to the times at the front and latter 10% peak heights, respectively, of the measured response curve $C_{\text{meas}}(t)$. The authors [9] evaluated that the ε values less than 1% were a good fit, and those less than 3% were an acceptably good fit. Note that u_0 is needed to obtain experimentally for the CIR method, while it is not required for the Taylor dispersion method.

3. Experimental

3.1. Apparatus and procedure

The diffusion coefficients of phenylbutazone were measured by the CIR and Taylor dispersion methods similar to that in the previous study [10]. A polymer-coated capillary open column (UACW-15W-1.0F, the Frontier Laboratories Ltd., Japan, polymer thickness of 1 μm , $R = 0.265$ mm, $L = 16.218$ m, and $R_{\text{coil}} = 310$ mm, where R_{coil} is the coil radius of diffusion column) and a non-coated capillary open column (bright annealed 316 Stainless-steel, GL Sciences Inc., Japan, $R = 0.416$ mm, $L = 16.634$ m, and $R_{\text{coil}} = 315$ mm) were employed as diffusion column in the CIR

method and the Taylor dispersion method, respectively. The diffusion column was immersed horizontally in the water bath (T-105, Thomas Kagaku Co., Ltd., Japan). The pressure of the system was controlled by a syringe pump (260D, ISCO, USA) and a back pressure regulator (Model SCF-Bpg/M, JASCO, Japan). A packed column was installed upstream at the regulator to stabilize the pressure. After the prescribed measurement conditions such as temperature, pressure, and flow rate of fluid had become constant, the system was held under the same conditions for at least a further two hours. Then, a pulse of phenylbutazone predissolved in ethanol was loaded through an injector (Model 7520, 0.5 μ L, Rheodyne, USA) into the fluid flowing. The response curves were monitored with a UV-Vis multi-detector (Model MD-1510, JASCO, Japan). Only a single pulse was injected for each measurement in this study.

84

3.2. Experimental conditions

Phenylbutazone (molecular formula: $C_{19}H_{20}N_2O_2$, molecular weight: 308.37) with purity 99% and ethanol with 99.5% were purchased from Wako, Japan. CO_2 with purity higher than 99.95% was obtained from Air Gases Tokai Ltd., Japan.

The measurements for D_{12} were carried out by the CIR method for phenylbutazone at 308.15, 313.15, 318.15, 323.15, 333.15, 343.15 K and pressures from 8.50 to 40.00 MPa in supercritical CO_2 . In addition the D_{12} values of phenylbutazone in ethanol were also measured by the Taylor dispersion method at 298.15, 303.15, 308.15, 313.15, 318.15, 323.15, 328.15, 333.15 K and at atmospheric pressure. At least three measurements were carried out for a given temperature and pressure, and the average value of the measurements was considered to be the D_{12} .

95

4. Results and Discussion

4.1. Effects of wavelength, secondary flow and injected amount

Fig. 1 shows the effects of absorption wavelength on (a) absorbance of the peak top of a response curve A_{max} , (b) $A_{max}/(u_0 \times \text{peak area})$, (c) D_{12} and (d) ε for phenylbutazone in supercritical

CO₂ at 313.15 K and 11.00 MPa measured by the CIR method. The response curves were measured at wavelengths from 200 to 300 nm at increments of 1 nm for each run. It was found that the absorbance intensities measured were lower than 0.2 AU. And the values of $A_{\max}/(u_0 \times \text{peak area})$ for the whole wavelength were constant, which evidences the linearity of the detector used in this study. Furthermore, the determined D_{12} values were almost constant except for the longer wavelengths (>290 nm) with lower $A_{\max}$ values. And the ε values showed lower values with less than 1% when wavelengths were lower than 290 nm. In this study all D_{12} values were determined from the response curves measured at 240 nm.

Fig. 2 represents the effects of CO₂ flow rate on D_{12} of phenylbutazone in supercritical CO₂ at 240 nm, 313.15 K and 11.00 MPa measured by the CIR method, together with the ε . The ε values for all data are lower than 1%, however the D_{12} values are affected by the flow rate due to the secondary flow caused by column coiling when $DeSc^{1/2} > 10$, where the Dean number $De = (2Ru_0\rho/\eta)(R/R_{\text{coil}})^{1/2}$, the Schmidt number $Sc = \eta/(\rho D_{12})$, the CO₂ density ρ was obtained from the literature [11,12], and the CO₂ viscosity η was from Fenghour et al. [13]. The leveled off value in Fig. 2(a) is adjudged to be the intrinsic D_{12} value. Note that the effect of the secondary flow was evaluated to be less than 1% in terms of the value of the moment when $DeSc^{1/2} < 8 \sim 9.5$ for the measurements by the CIR method [14] and when $DeSc^{1/2} < 8$ for the measurements by the Taylor dispersion method [8]. All measurements were made at $DeSc^{1/2} < 8$ in this study.

Fig. 3 plots the effects of the injected amounts m of phenylbutazone on (a) $A_{\max}$, (b) $u_0 \times (\text{peak area})$, (c) D_{12} and (d) ε measured by the CIR method in supercritical CO₂ at 240 nm, 313.15 K and 11.00 MPa. Six difference solutions of phenylbutazone in ethanol over the wide range of the solute concentrations (3.48×10^{-5} , 3.48×10^{-4} , 2.00×10^{-3} , 3.48×10^{-3} , 1.00×10^{-2} and 3.48×10^{-2} g mL⁻¹) were used. Correspondingly the injected amounts of phenylbutazone were 5.64×10^{-5} , 5.64×10^{-4} , 3.24×10^{-3} , 5.64×10^{-3} , 1.62×10^{-2} and 5.64×10^{-2} μmol , respectively. As shown in Fig. 3(b), the values of $u_0 \times (\text{peak area})$ are proportional to m with the slope of about 1. For the injected amounts from 5.64×10^{-5} to 5.64×10^{-2} μmol , all D_{12} values are nearly constant, as observed from Fig. 3(c),

126 and the ε values are lower than 3%. In this study all measurements were carried out with 3.48×10^{-3}
 127 g mL⁻¹ ethanol solution of phenylbutazone.

128

129 4.2. Diffusion measured by the CIR method

130 The effect of pressure on D_{12} of phenylbutazone measured by the CIR method in supercritical
 131 CO₂ is presented in Fig. 4 and the D_{12} data are listed in Table 1. The D_{12} data were measured
 132 isothermally as a function of pressure from 8.50 to 40.00 MPa at 308.15, 313.15, 318.15, 323.15,
 133 333.15 and 343.15 K. Note that only the D_{12} data whose ε values were less than 1% were adopted
 134 for all measurements in this study. It was observed that the D_{12} values simply decreased with
 135 increasing pressure and decreasing temperature, and then the slopes gradually decreased. The
 136 influence of pressure on D_{12} was less significant at higher pressures. This behavior has been
 137 reported in recent studies [15-31]. On the other hand, the higher pressure sensitivity of D_{12} in the
 138 low pressure range can be found, which is probably due to significantly changes in density and
 139 viscosity in this region. As has been seen, the D_{12} data can be represented by a simple empirical
 140 correlation with temperature and pressure (Eq. (3)) with the average absolute relative deviation
 141 (AARD) of 2.8% for 104 data points, while the correlation depends on the system studied.

$$142 \quad D_{12} = 5.92 \times 10^{-9} - 7.51 \times 10^{-12} T - \frac{8.49 \times 10^{-7}}{P} + 2.89 \times 10^{-9} \frac{T}{P} \quad (3)$$

$$143 \quad \text{AARD} = \frac{1}{N} \sum_{i=1}^N \left| \frac{D_{12,i,\text{crl}} - D_{12,i,\text{meas}}}{D_{12,i,\text{meas}}} \right| \times 100\% \quad (4)$$

144 where D_{12} , T and P are in m² s⁻¹, K and MPa, respectively, N is the number of experimental points,
 145 and $D_{12, i, \text{crl}}$ and $D_{12, i, \text{meas}}$ are the correlated and measured data, respectively. Although the Eq. (3) is
 146 in excellent agreement with the D_{12} data in the higher pressure region, which also can be seen in
 147 literature [24,26-29], there is a significant deviation from the experimental data in the lower
 148 pressure region at each constant temperature.

149

4.3. Diffusion measured by the Taylor dispersion method

The effect of temperature on D_{12} of phenylbutazone measured by the Taylor dispersion method in ethanol at 298.15, 303.15, 308.15, 313.15, 318.15, 323.15, 328.15 and 333.15 K is presented in Fig. 5 and the D_{12} data are shown in Table 2. The D_{12} data were measured isobarically as a function of temperature at atmospheric pressure. The D_{12} values increased with increasing temperature at constant pressure. And a high temperature dependence on D_{12} can be observed.

4.4. Predicting all data

Fig. 6 shows D_{12}/T as a function of fluid viscosity η for all D_{12} data of phenylbutazone in supercritical CO₂ measured by the CIR method and in ethanol measured by the Taylor dispersion method in this study. Note that the ethanol viscosities were obtained from the literature [32]. The data can be represented with straight lines given by Eq. (5).

$$\frac{D_{12}}{T} = \alpha \eta^{\beta} \quad (5)$$

where α and β are parameters, which are specific to the system of a solute and a fluid. The validity of the correlation in Eq. (5) on the basis of the hydrodynamic approach has been demonstrated for various compounds in supercritical CO₂ [15-23,25,30,31], in organic solvents [33,34] and mixture [35] of supercritical CO₂ and hexane. It was found that all data for the two studied systems of phenylbutazone in CO₂ and phenylbutazone in ethanol also can be represented by Eq. (5). We obtain $D_{12}/T = 2.346 \times 10^{-15} \eta^{-0.955}$ with AARD of 5.4% for 112 data points, where D_{12} , T and η are in m² s⁻¹, K and Pa s, respectively.

5. Conclusion

Infinite dilution binary diffusion coefficients of phenylbutazone in supercritical CO₂ at 308.15, 313.15, 318.15, 323.15, 333.15, 343.15 K and 8.50 to 40.00 MPa were measured by the CIR method. In addition the D_{12} data of phenylbutazone in ethanol were measured at 298.15, 303.15,

308.15, 313.15, 318.15, 323.15, 328.15, 333.15 K and atmospheric pressure by the Taylor dispersion method. The values of D_{12} for phenylbutazone were determined by fitting the response curve calculated to that measured experimentally. It was found that the D_{12} increased from $4.447 \times 10^{-10} \text{ m}^2 \text{ s}^{-1}$ at 298.15 K and 0.1 MPa in ethanol to $1.434 \times 10^{-8} \text{ m}^2 \text{ s}^{-1}$ at 343.15 K and 14.00 MPa in supercritical CO_2 . All experimental data were able to be correlated with the hydrodynamic equation D_{12}/T as a function of fluid viscosity with a wide viscosity range (3.232×10^{-5} to $1.113 \times 10^{-3} \text{ Pa s}$) from supercritical to liquid state, and the results showed a good agreement between the correlated results and the experimental data with AARD of 5.4% for 112 data points.
